PEPPOL Transport Infrastructure ICT - Models

PEPPOL Directory

Version: 1.1 Draft 20180717

Status: In use

Editors:

Philip Helger, BRZ Ger Clancy, IBM

Revision History

Version	Date	Description of changes	Approved by
	2015-08-03	Updated details on the PD-SML connection	PH
		Editorial changes in 5.2.2, 6.1.1	
		Changed link in chapter 7	
	2015-09-10	Moved chapter 4.1.5 to become 4.1.1	PH
		Fixed example requests in the PD Indexer section	
		Fixed HTTP return codes in Indexer section	
		Added chapter 4.1.7 on internal processing	
	2016-01-20	Updated to PEPPOL Directory	PH
		Adopted to separate SMP interface	
		Adopted to new XSD	
	2016-04-22	Introduction less technical	PH
		Logical separation between Publisher and Indexer less important	
	2016-11-28	Updated to MC decisions	PH
		Stripped down Business Card data	
1.0	2016-12-05	Updated contributor list	PH
	2017-04-03	Updated REST API description slightly	PH
1.1	2018-07-16	Updated REST API to match implementation	PH
		Chapter 5.2: fixed example; added note on encoding	
		Added chapter "Usage outside of PEPPOL"	
		The BC data model now has a multilingual entity name	
		Minor editorial corrections and clarifications added

11 1 Introduction

- 12 The goal of this document is to describe the architecture and interfaces of the PEPPOL Directory (PD;
- 13 formerly known as PEPPOL Yellow Pages) project. The goal of the PD project is to create a publicly
- 14 available, searchable list of all PEPPOL participants with their respective metadata like company
- 15 name, country code, etc. (for details see chapter 4.1). The PD is not meant to replace existing PEPPOL
- 16 components but to be an aggregator for data that is contained in existing PEPPOL SMPs.
- 17 An additional singleton service is added to the PEPPOL infrastructure: the so-called **PD Server**. It is
- filled with electronic **Business Cards** of the PEPPOL participants on a voluntary basis meaning that
- 19 SMP providers can (but are not forced to) publish their client's metadata in the PD. The data is stored
- 20 in correlation with the SMP entry of the respective participant (aka service group). Details are
- 21 described in chapter 4.2. SMP providers MUST provide the technical interface no later than October
- 22 31st 2018 and MAY publish client's metadata.
- 23 This document describes the architecture of the PD server, the interfaces to and from it as well as the
- 24 data format for the Business Cards (see chapter 4) within the SMP. This document concludes with a
- 25 high level technical description on how the PD Server is implemented.

26 2 Why PEPPOL Directory?

- 27 Due to variations between countries and markets, there are no shared models on how to know the
- 28 PEPPOL Participant ID (PPID) of the sender, further enforced by the lack of open national business
- 29 registries. Knowing each other in domains of limited size, for example e-CODEX project in e-Justice, is
- 30 easy, however in domains like PEPPOL having potentially millions of organizations it is impossible.
- 31 Trying to solve the problem of finding each other, PEPPOL Directory (PD) is introduced, a central
- 32 service to query based on given metadata. Querying may be part of a manual or automated process
- 33 before performing lookup in SML (Service Metadata Locator) and SMP (Service Metadata Publisher).
- 34 PD contains indexed PEPPOL Directory Business Cards (BC) containing metadata related to a given
- 35 PPID. The lack of a PEPPOL Directory is a constraint to wider scale adoption of PEPPOL by small and
- 36 medium sized enterprises.

2.1 Use Cases

- 38 The PEPPOL Directory is intended to support business cases that are concerned with finding PEPPOL
- 39 participants registered on the PEPPOL network, in order to start exchanging business documents
- 40 with them. Some of the possible business cases are identified below.

41 2.1.1 New PEPPOL BIS support - Matching

- 42 An organization that has recently become a PEPPOL participant, wishing to exchange a particular
- 43 PEPPOL BIS, as a Customer or a Supplier, will want to find who of their trading partners are capable
- of exchanging the same BIS documents in the opposing role.

- 45 As example an organization that is starting to send invoices may want to know which of their
- 46 customers can receive them and an organization that is starting to receive invoices will want to know
- 47 which of their suppliers can send them.

48 2.1.2 Monitoring new PEPPOL users - Alerting

- 49 An organization that is using PEPPOL to exchange one or more PEPPOL BIS may want to monitor
- 50 when more of their trading partners become PEPPOL participants and consequently to automate
- their trading relations with them by using PEPPOL.

52 2.2 Planned key functions of PEPPOL Directory

- The following key functions are planned for the PEPPOL Directory and will be implemented through
- 54 different releases of the Directory. These features are intended to support the business use cases
- described in the previous chapter.

56 2.2.1 Free text search

- 57 A free text search allows the Directory user to enter a text string into an online form and get a list of
- 58 result for all listings in the Directory where that string appears. As an example, if the user enters the
- 59 word "Acme" he will get a list of all participants who's name contains the word "Acme" as well as
- 60 participants where the word "Acme" appears in other elements of the Business Card.
- 61 The user can browse the list to find the PEPPOL participant he is looking for and then click on his
- 62 choice to see the full details.

63 2.2.2 Identifier search

- The directory specification supports the use of qualified identifiers for the search. The objective is to
- 65 enable single match searches where the user submits a query on whether there exists a user, with a
- 66 particular identifier and BIS capabilities. This enables searching by VAT, legal identifiers and other
- 67 parameters that are commonly known but may differ from the PEPPOL end point identifiers. As an
- 68 example, a user may want to find the end point identifier for a customer who has a particular VAT
- 69 identifier. By restricting the search to a particular capability, he can use the query to monitor when
- 70 that customer starts to support the given documents.

71 2.2.3 API connection

- 72 The PEPPOL Directory will also enable Directory users to let their systems connect automatically
- 73 instead of manually browsing through a web interface. This supports automated searches that can be
- 74 integrated into the sending process.
- 75 A drawback to be considered is that the publication of the Business Cards in the PEPPOL Directory
- happens on a voluntary basis.

2.3 Considerations

- 78 The following considerations influencing the development of the PEPPOL Directory have been
- 79 identified but require additional analysis.

80 2.3.1 Searching for senders

- 81 The current architecture of the PEPPOL network does not require PEPPOL Participants who are only
- sending documents to be registered in the SMP's and consequently they are not in the SML. This
- limits the capability of the PEPPOL Directory to include these PEPPOL participants in search results.
- 84 This relates to other issues that are currently being addressed in other PEPPOL initiatives. A potential
- 85 change in the PEPPOL policy that requires registration of senders would benefit the PEPPOL Directory
- without requiring additional changes to the PD.
- 87 Alternatively sending only participants may be registered to an SMP with an empty service group
- 88 which allows them to publish Business Cards for the PEPPOL Directory as well.

89 2.4 Usage outside of PEPPOL

- 90 This specification and the software components were originally created for the usage within PEPPOL.
- 91 As other projects also showed interest in reusing these artefacts it can be clearly stated, that the
- 92 components described herein can be reused in different scenarios unrelated to PEPPOL. E.g. the
- 93 TOOP project (www.toop.eu) uses PEPPOL Directory as "TOOP Directory" inside their dynamic
- 94 discovery component to find multiple receivers using the REST query API.

95 3 PD Server architecture

- 96 This section describes the overall architecture of the PD Server. It logically consists of two major
- 97 parts: a *PD Indexer* which is responsible for creating, updating, deleting and indexing the Business
- 98 Card data and the PD Publisher which is the public web frontend to the PD for both humans and
- 99 machines.

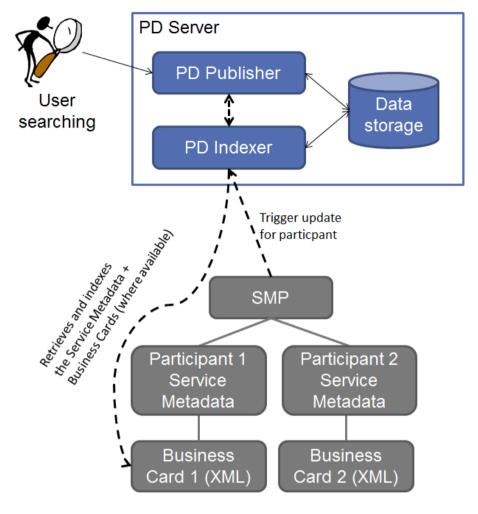

Figure 1: PD big picture without SML

The above big picture outlines the information flow. If a participant's business card is added to, updated to or deleted from an SMP, the SMP MAY trigger an update to the *PD Indexer* (see arrow from SMP to the *PD Indexer* in the figure) even if the Business Card contained in the SMP is empty. If data is to be added or updated on the PD, the *PD Indexer* will retrieve the complete Business Card from the respective SMP and index it for searchability (see arrow from PD Indexer to *Business card* in the figure).

If a user wants to know whether a certain company is registered in the PEPPOL network he opens the web site of the *PD Publisher*, types the search term (e.g. the company name) and a list of potential hits (including the PEPPOL participant identifier and the supported PEPPOL document types) shows up. In addition to the human interface, a REST interface for automatic searching is offered. The *PD Publisher* retrieves all relevant information directly from the *PD Indexer* so that no interaction with the concerned SMPs is necessary.

An extension to the *PD Indexer* is the direct connection to the SML to retrieve a list of **all** registered PEPPOL participants. In this case the PD Indexer will query the SML regularly (e.g. once a week) for a

complete participant list and queries the respective SMPs independent of the SMP provided update status.

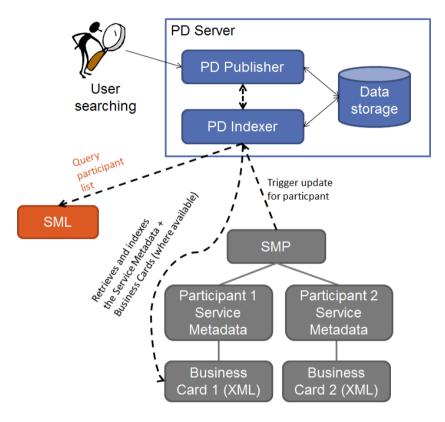

Figure 2: PD big picture with SML

As shown in the previous figure the overall architecture is only extended to interconnect with the SML and no other changes are necessary. The SML already offers an interface to retrieve a list of all registered PEPPOL participants and is therefore prepared to be interconnected with the PD.

Early benchmarks on the SML test machine (being slower than the production machine) showed that a list with 100.000 entries can be created in 16 seconds and 150.000 entries took 34 seconds. By middle of 2018 approx. 112.000 entries were in the production database.

4 Business card

4.1 Data format

This section describes the layout of the business card data that is stored in an SMP. Because the scope of a single PEPPOL participant within an SMP can be very broad, the data format must be capable of handling information for more than one business entity in a structured way. Sometimes a PEPPOL participant may even link to different entities in different countries.

Existing formats like vCard, xCard or the UBL 2.1 Party type were not considered because they are either not XML or too complex to interpret fully. Instead a new minimal XML-based format is created

134	because PEPPOL participant identifiers are used very differently it was decided to use a very flexible
135	scheme that can represent multiple business entities at once.
136	The format defines a single business card consisting of the following fields:
137	PEPPOL participant ID
138	 Description: PEPPOL participant identifier corresponding to a service group hosted
139	on the same SMP
140	 Multiplicity: 11 (mandatory)
141	PEPPOL document type ID
142	 Descriptions: all PEPPOL document type identifiers as indicated by the default SMP
143	service group query.
144	 Multiplicity: 0n (optional but potentially many)
145	Business entity
146	 Description: a business entity that can be reached via the provided PEPPOL
147	participant ID
148	 Multiplicity: 0n (optional but potentially many)
149	Each business entity consists of the following fields:
150	Entity name
151	 Description: the company name or the name of the governmental entity. It may
152	include an optional language in ISO 639-1 format (e.g. "de" for German) per entity
153	name.
154	 Multiplicity: 1n (mandatory but potentially many)
155	Country code
156	 Description: the country code in ISO 3166-2 format (e.g. "AT" for Austria)
157	 Multiplicity: 11 (mandatory)
158	Geographic information
159	 Description: describes the location or region of the entity that is usually used to
160	identify the entity. This may be an address, a state name etc.
161	 Multiplicity: 01 (optional)
162	Identifier
163	 Description: additional (non-PEPPOL) identifiers of the entity that are not part of the
164	PEPPOL participant identifier. It consists of a type and a value. This can e.g. be a
165	national VAT identification number; a national company register number etc. The
166	following identifier types (case insensitive) must at least be supported by the
167	Directory:
168	"vat" – VAT identification number including the national prefix
169	"orgnr" – the national organisation number
170	"gln" – Global Location Number (GLN)
171	"duns" – DUNS number

Multiplicity: 0..n (optional but potentially many)

• Registration date

174

- Description: the date when the participant joined the PEPPOL network
- o Multiplicity: 0..1 (optional)
- 176 The link to the XML Schemas describing the layout of the Business Card can be found in chapter 7 of
- 177 this document. To support future updates of this Business Card scheme the XML root element
- 178 (BusinessCard) has an XML namespace URI that allows for easy versioning of the contained data.
- 179 Version 1 of the XML schema for the business card uses the XML namespace URI
- 180 http://www.peppol.eu/schema/pd/businesscard/20161123/.
- 181 A non-normative example Business Card with a single entity looks like this:

```
182
      <BusinessCard
183
          xmlns="http://www.peppol.eu/schema/pd/businesscard/20161123/">
184
        <ParticipantIdentifier</pre>
185
            scheme="iso6523-actorid-upis">0088:example</ParticipantIdentifier>
186
        <BusinessEntity registrationDate="2010-07-06">
187
          <Name>ACME Inc.</Name>
188
          <CountryCode>AT</CountryCode>
189
          <GeographicalInformation>ACME street 123</GeographicalInformation>
190
          <Identifier scheme="VAT">ATU12345678</Identifier>
191
          <Identifier scheme="OrgNr">hjdh7as9ds</Identifier>
192
        </BusinessEntity>
193
      </BusinessCard>
```

194 4.2 SMP impacts

- 195 This chapter describes the constraints for storing Business Cards in an SMP and how to access the
- 196 Business Cards from the outside world.²
- 197 **4.2.1 Storage**

206

207208

- 198 This section describes how and where Business Cards are to be stored in an SMP. The SMP
- 199 differentiates between service groups and service registrations. A service group is basically the
- 200 PEPPOL participant identifier whereas a service registration is the combination of a participant
- 201 identifier, a document type, a process identifier, a transport protocol and an AP endpoint URL (plus
- 202 some additional information).
- 203 Each Business Card must be stored in relation to a single SMP service group. There are no predefined
- rules how this is to be achieved as the data storage mechanisms of an SMP server are quite different
- in practice. The only binding rules are:
 - 1. An SMP MUST NOT provide Business Cards for service groups not owned by this SMP.
 - 2. Each service group MAY have zero or one associated Business Card.
 - 3. The link between the Service Group and the Business Card MUST be the PEPPOL participant ID.

² phoss SMP and IBM SMP have already implemented support for the BusinessCard API in their solutions.

- 210 Originally it was considered to store the Business Card information in the Extension element of an
- 211 SMP Service Group. The positive aspects of this solution are that the data model of existing SMPs
- does not need to be altered and that no new APIs for the SMP must be provided. The negative
- aspects of this solution are that the network traffic for non-PD queries would heavily increase and
- 214 the general performance of SMPs might be downgraded and that non-relevant information would be
- 215 returned in regular Service Group queries. An additional problem with this solution is that the
- 216 PEPPOL SMP specification is lacking support for multiple extensions in a single service group which in
- turn would require an additional non-standard "extension container" to maintain extensibility. OASIS
- 218 BDXR SMP CS03 adds supported for multiple extensions.
- 219 4.2.2 Public REST interface
- 220 To retrieve the Business Cards from an SMP server a new REST interface is introduced. This interface
- 221 must be provided by all SMP servers that want to serve Business Card data for the PD. REST was
- 222 chosen because the existing SMP interfaces are already REST based and therefore no new technology
- is introduced.
- 224 4.2.2.1 Retrieve Business Card interface
- 225 REST request: GET /businesscard/{participantID}
- 226 | Note: {participantID} is the placeholder for the effective PEPPOL participant identifier in the
- 227 URL encoding form
- 228 REST response: the XML representation of the Business Card (according to an XSD specified in
- chapter 7) preferably in UTF-8 encoding using MIME type application/xml.
- 230 REST response code:
- HTTP 200 (OK) everything was ok. A response body is send back.
- HTTP 404 (Not found) no Business card was found for the provided participant ID.
- + HTTP 500 (Internal server error) something internally went wrong. Response body contains
 the details in plain text.
- Non-normative example to query the business card for PEPPOL participant 9915:test on the SMP
- 236 server running at http://smp.example.org:
- http://smp.example.org/businesscard/iso6523-actorid-upis%3A%3A9915%3Atest
- The response may look like the example provided in section 4.1.
- Note: using PEPPOL participant identifiers directly in URLs may impose problems. It must be ensured
- that the colon character (":") is escaped as %3A in the URL.
- Note: this interface must also work with the computed "B-....edelivery.tech.ec.europa.eu" URLs.
- 243

Note: as a future extension, the response of the SMP may be signed with the respective SMP certificate.

246	5 PD Indexer
247	This chapter describes the technical details of the PD Indexer. It describes the data elements that
248	must be passed to the PD Indexer so that Business Cards can be created, updated, deleted or
249	retrieved. This is a REST interface, because the SMP server (that will trigger this interface) is also a
250	REST server and therefore the technology is well known and supported.
251	All REST interface URLs contain a version number so that it will be easy to provide updated interfaces
252	in the future without breaking the existing ones.
253	5.1 Authentication and authorization
254	Note: this section is only applicable, it the PD Indexer runs on a server that offers secure HTTP
255	connections (https).
256	For security reasons, only legitimate SMPs are allowed to request modifications in the <i>PD Indexer</i> . To
257	ensure this all HTTP calls to the PD Indexer interface must provide a client X.509 certificate. This is
258	the same technology that is already used in the SMP to SML communication and should therefore be
259	implementable in a quick and easy way. Requests to the PD Indexer without a client certificate will
260	result in an error.
261	The provided client certificate must be the SMP certificate as used for the communication with the

263 5.2 Adding a participant

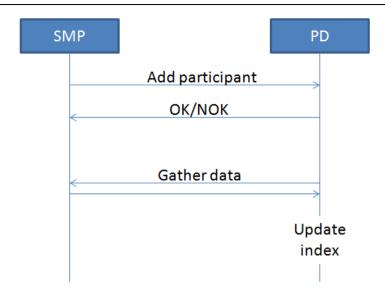

262

SML.

- 264 For adding a participant, only the participant identifier must be passed to the *PD Indexer*. The
- 265 Business Card is read directly from the respective SMP (determined via DNS lookup) and is not
- passed in this call. This allows the *PD Indexer* to build a queue of items to be updated in an optimized
- way, and also avoids overwriting data of participants that are owned by different SMPs.

272

273

276

279

280

281282

283

284

285286

287288

289

Figure 3: Add participant workflow

270 REST request: PUT /indexer/1.0/

271 Request body: {participantID}

Note: {participantID} is the placeholder for the effective PEPPOL participant identifier in URL encoded form

- 274 Example request:
- URL: PUT /indexer/1.0/
 - Body: iso6523-actorid-upis::0088:gln1234
- Note: the participant identifier MUST NOT be URL encoded.
- 278 REST response code:
 - HTTP 204 (OK, No content) everything was ok. No response body is send back.
 - HTTP 403 (Forbidden) no client certificate or an invalid client certificate provided
 - HTTP 500 (Internal server error) something internally went wrong. Response body contains the details in plain text.

Note: This requires the DNS entry of the added PEPPOL participant already being available publicly to resolve the owning SMP. Therefore an SMP MUST call the PD after the registration at the SML. The *PD Indexer* will handle added participants gracefully if the respective DNS entry is not yet present and will retry at a later point in time. If a new participant DNS entry is not present within a configurable duration related to the original indexing request, this particular request is discarded and therefore no indexing takes place. If previous indexed information of that participant is present (if it is an updating call) they are left unchanged.

301

302

303

304

5.3 Modifying an existing participant

If the Business Card of an existing participant is modified the *PD Indexer* must be informed about the change. The API and the constraints are identical to "Adding a participant" (see chapter 5.2).

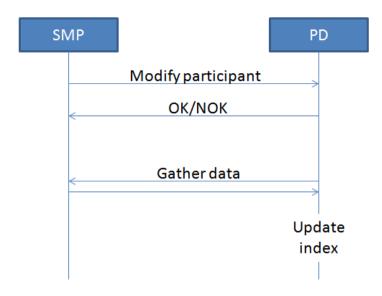

Figure 4: Modify participant workflow

Note: there is no possibility to identify whether the participant was added or updated by the response. To check for existence, use the GET operation defined below.

5.4 Deletion of a participant

When a service group in the SMP is about to be deleted (either because the participant leaves the PEPPOL network or because an SMP migration takes place), the *PD Indexer* must be notified. To delete participant information in the *PD Indexer* it is suitable to provide only the respective PEPPOL identifier.

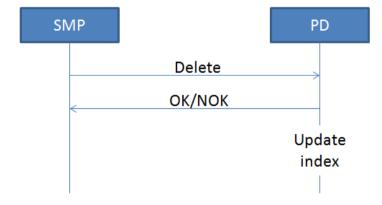

Figure 5: Delete participant workflow

REST request: DELETE /indexer/1.0/{participantID}

305 306	Note: {participantID} is the placeholder for the effective PEPPOL participant identifier in URL encoded form
307	Example request:
308	• DELETE /indexer/1.0/iso6523-actorid-upis%3A%3A0088%3Agln1234
309 310	Note: using PEPPOL participant identifiers directly in URLs may impose problems. So ensure that the colon character (":") is escaped as %3A in the URL.
311	REST response code:
312 313 314 315	 HTTP 204 (OK, No content) – everything was ok. No response body is send back. HTTP 403 (Forbidden) – no client certificate or an invalid client certificate provided HTTP 500 (Internal server error) – something internally went wrong. Response body contains the details in plain text.
316 317	Note: if a participant is moved from one SMP to another it must first be deleted by the old SMP and then re-created by the new SMP.
318	
319 320 321 322	Note: the delete operation may impose a security problem because one SMP can delete the information of a participant created by a different SMP. Therefore the deletion does not directly delete the information in the index but only marks the respective records internally as "deleted" so that the data can be restored in case of a misuse.
323 324 325	5.5 Existence check of a participant Checking whether a Business Card of a participant is present in the <i>PD Indexer</i> can be performed via the following interface:
326	<pre>REST request: GET /indexer/1.0/{participantID}</pre>
327 328	Note: {participantID} is the placeholder for the effective PEPPOL participant identifier in URL encoded form
329	Example request:
330	• GET /indexer/1.0/iso6523-actorid-upis%3A%3A0088%3Agln1234
331 332	Note: using PEPPOL participant identifiers directly in URLs may impose problems. So please ensure that the colon character (":") is escaped as %3A in the URL.

333 REST response code:

334

- HTTP 204 (OK, No content) Yes, the participant is already in the *PD Indexer*.
- HTTP 403 (Forbidden) no client certificate or an invalid client certificate provided

- HTTP 404 (Not found) the participant is not in the *PD Indexer*.
 - HTTP 500 (Internal server error) something internally went wrong. Response body contains the details in plain text.

Note: because of the internal asynchronous processing, it might take some time after an index request until the participant is available in search results. See chapter 5.7 for more details.

341342

347

337

338

339

340

Note: calling this API also requires the presence of a client certificate.

343 5.6 Auditing and Logging

- 344 All successful calls to the PD Indexer (create/update/delete/get) are logged together with the
- 345 timestamp, the source IP address and some information from the provided certificate (country,
- 346 subject name and serial number) to ensure traceability of the performed actions.

5.7 Internal processing of the data

- 348 Internally the Indexer keeps a FIFO work queue that is processed asynchronously. All new indexing
- requests (create/update/delete) are put into that queue and wait for their serial processing to avoid
- overloading a single SMP with queries. That's why deletion (see chapter 5.4) may not trigger an
- immediate return code like "not found" because the result is not known synchronously.
- 352 If the data retrieval from the SMP fails (for whatever reason) the work item is put into a special "retry
- 353 queue" and the data retrieval is retried some time later (suggested duration until retry is 5 minutes –
- must be configurable). If an entry cannot be indexed after a certain period of time (suggested period
- is 24 hours must also be configurable), it is moved to a "dead work item queue". In case of a
- permanent failure manual intervention is necessary. E.g. the PD administrator may re-trigger the
- work item manually or choose to drop it completely.
- 358 The asynchronous processing may impose problems when trying to check for the existence of a
- 359 certain participant identifier in the index. This check will only return success if the item was already
- processed and stored in the index but not if it is still in the work queue.

5.8 Internal data structure

- 362 The internal data structure of the PD Indexer is slightly different from the Business Card entities
- defined in chapter 4.1. Besides the Business Card content, the following data elements should also be
- 364 stored:

361

365

366

367

368

369 370

- All supported PEPPOL document type identifiers as listed by the SMP service group interface.
 Therefore, a separate SMP query on the ServiceGroup must be performed and the document types must be extracted.
- The unique identifier taken from the client certificate that triggered the indexing of the document (the "requestor"). This can e.g. consist of the certificates subject name, serial number and country code.
- The date and time when the Business Card was last indexed.

372 6 PD Publisher

- 373 This section describes the components of the PD Publisher. It consists of a machine-to-machine
- 374 search interface as well as a search interface for humans as well as a list of registered PEPPOL
- 375 participants for download. Additional features can be integrated into the Publisher after the initial
- 376 version.
- 377 Currently two implementations are available:
- 378 https://directory.peppol.eu (production server)
- 379 https://test-directory.peppol.eu (test server)

380 6.1 Search interface

- This section only describes the machine-to-machine search interface. It uses REST as the protocol and
- 382 responds with XML or JSON data.

383 **6.1.1** Request

390

391

392393

394

395

396

397398

- The relative base URL of the REST search service is /search/1.0/[format] which is then
- followed by a list of query parameters as outlined below. The [format] placeholder in the request
- API denotes the desired response format. Initially xml (for XML output) and json (for JSON output)
- 387 are supported but other formats might be added as future extensions. All search REST requests are
- 388 HTTP GET requests. Other HTTP methods like POST, PUT etc. are not supported.
- The search routines use the following text matching algorithms:
 - Exact match (case sensitive): the search term and the indexed values must be completely equal, including case sensitivity.
 - Exact match (case insensitive): the search term and the indexed values must be completely equal, excluding case sensitivity.
 - Partial match: the search term must be equal or fully contained in the indexed value in a case
 insensitive way (e.g. searching for "tici" or "TICI" in the indexed value "participant" will be a
 match)
 - Starts with match: a special version of the partial match that requires the indexed value to begin with the search term in a case insensitive way (e.g. search for "part" or "PART" will match "participant" but "art" won't match "participant")

Parameter name	Explanation
q	General purpose query term. This term is searched in all fields with the matching rules of the respective fields. Multiple search terms can be provided separated by a whitespace character. If multiple search terms are provided, they are interpreted as "AND" operators, so only results with all query terms are returned.
participant	Searches for <i>exact matches</i> (case insensitive) in the participant identifier field (the identifier scheme must be part of the value).
name	Searches for <i>partial matches</i> in the <i>entity name</i> field.

	Only search terms consisting of at least 3 characters are used for search. This parameter can occur more than once.
	Tokens are not split when using this parameter.
country	Searches for exact matches (case insensitive) in the country code field.
	This parameter can theoretically occur more than once but it does not make
	sense, because a business card cannot have more than one country.
geoinfo	Searches for <i>partial matches</i> in the <i>geographic information</i> field.
	Only search terms consisting of at least 3 characters are used for search.
	This parameter can occur more than once.
	Tokens are not split when using this parameter.
identifierScheme	Searches for exact matches (case insensitive) in the additional identifier type field
	(only the type, not the value).
	Tokens are not split when using this parameter.
	Combine this field with identifierValue field for fine-grained searching.
identifierValue	Searches for exact matches (case insensitive) in the additional identifier value
	field (only the value, not the type).
	Tokens are not split when using this parameter.
	Combine this field with identifierScheme field for fine-grained searching.
website	Searches for <i>partial matches</i> in the <i>website</i> field.
	Only search terms consisting of at least 3 characters are used for search.
	This parameter can occur more than once.
	Tokens are not split when using this parameter.
contact	Searches for <i>partial matches</i> in the <i>contact</i> fields (type, name, phone number
	and email address).
	Only search terms consisting of at least 3 characters are used for search.
	This parameter can occur more than once.
	Tokens are not split when using this parameter.
addinfo	Searches for <i>partial matches</i> in the <i>additional information</i> field.
	Only search terms consisting of at least 3 characters are used for search.
	This parameter can occur more than once.
	Tokens are not split when using this parameter.
regdate	Searches for exact matches in the <i>registration date</i> field. The value of the date to
	search must be provided in the format 'YYYY-MM-DD' (ISO 8601/XML Schema
	based date format).
1	The parameter supports neither a time nor a time zone.
doctype	Searches for exact matches (case sensitive) in the document type identifier field
	(the identifier scheme must be part of the value).

400 If multiple of the query parameters are used together only the results matching ALL query terms are 401 returned (like a boolean AND operation).

The following table contains the additional parameters that can be used to control the result subset:

Parameter name	Explanation
resultPageIndex	The result page to be shown. If this parameter is not present the first page is
	returned. The result page index is 0-based meaning that the first page has index
	0. The index of the first search result returned is calculated by
	resultPageIndex * resultPageCount

resultPageCount	The number of results to be returned on a single page. If this parameter is not present 20 results are returned by default.
beautify	Format the results so that they are more human readable? This should only be
	used for debugging purposes as it increases the transferred data volume. By
	default the returned code is minified.

- 404 **6.1.2** Response
- If no query term parameter (see table in chapter 6.1.1) is provided the return value is HTTP 400 (Bad Request).
- In addition to the result Business Cards, each response contains the following fields (in a syntax-specific way):

Field name	Explanation
version	The version of the response layout, defining the contained fields. This is only present to handle future modifications. The current version is 1.0 .
	-
total-result-count	The total number of matching documents.
used-result-count	The number of results contained in the response. This is always ≤ total-result-
	count as it is based on the paging parameters used.
result-page-index	The 0-based index of the result page.
result-page-count	The number of entities to show on a single page.
first-result-index	The effective 0-based index of the first result item returned (inclusive). This is the result of
	result-page-index * result-page-count.
last-result-index	The effective 0-based index of the last result item returned (inclusive). This is the result of
	min ((result-page-index + 1) * result-page-count - 1, total-result-count - 1).
query-terms	The combined query string that was used to perform a search. This is mainly for
	debugging purposes to cross-check which parameters took effect in searching.
creation-dt	The UTC date and time when this response was created. If possible it is formatted according to XML Schema (XSD) rules.

409

410 411

412

413 414

415

Note: the PD Publisher will deliver at most the top 1.000 results. If the combination of resultPageIndex and resultPageCount results in too small (< 0) or too large values (> 1000) the return value is HTTP 400 (Bad Request). The index of the first search result returned is resultPageIndex * resultPageCount. The index of the last search result returned is (resultPageIndex + 1) * resultPageCount - 1.

6.2 User interface (non-normative)

- 416 6.2.1 Use case Search
- The PD Publisher must offer a publicly available web page where the user can enter search terms to
- 418 search for one or more PEPPOL participants. It should provide a simple search form where only a set

419 420	of terms can be entered and the <i>PD Publisher</i> will search for the best possible matches. Additionally, an extended search form with all fields (as outlined in chapter 6.1.1) should be available.
421	The search results will be shown on the website and will also be made available for download.
422 423 424 425	6.2.2 Use case Browse The PD Publisher should offer a list of all registered business entities so that the information is browsable or even downloadable as e.g. an Excel document. This implies that the full data must be stored in the PD Indexer.
426 427 428	7 Annex A - Business Card XSD The PEPPOL Directory implementation supports multiple Business Card formats. The official Business Card XML Schemas can be found in the following folder:
429 430	https://github.com/phax/peppol-directory/tree/master/peppol-directory-businesscard/src/main/resources/schemas
431	The details in the versions are as follows:
432	 peppol-directory-business-card-20160112.xsd
433	 This is the original proposal of the data format
434	 It contains a single entity name without a language
435	 peppol-directory-business-card-20161123.xsd
436	 This is the official data format version 1
437	 Compared to 20160112 it does not contain the fields "AdditionalInformation",
438	"Contact" and "WebsiteURL" but for the rest it is identical.
439	 It contains a single entity name without a language
440	 peppol-directory-business-card-20180621.xsd
441	 An extension to the 20160112 format
442	 It allows to specify more than one name in different languages
443	 This is the preferred version to implement
444	8 Annex B - Implementation proposal (non-normative)
445	This section roughly describes, how the <i>PD Server</i> could be implemented and how existing SMP
446	servers could be modified to interact with the PD server.
447	All data described in this document must be stored and/or transmitted in UTF-8 character encoding
448	set. Using other character encodings is prohibited.

The rest of this chapter assumes that the development is done with Java.

450 **8.1 PD Server**

- 451 For simplicity the *PD Server* should be implemented as a regular Java web application that is runnable
- on a regular servlet container like Apache Tomcat or Jetty. It internally consists of two main parts:
- 453 the PD Indexer and the PD Publisher. Both components have to expose a component to the outside
- world but need to fulfil different tasks.

455 **8.1.1 PD Indexer**

459

460 461

462

463 464

465 466

467 468

469

470

471

- 456 The PD Indexer is responsible for gathering the business cards from the different SMPs and storing it
- into a searchable index. It is also responsible for periodically grabbing all participants from the SML.
- 458 The basic components are:
 - A "work queue" that handles the requested actions for certain participants with a certain
 priority handling (requests from SMPs have a higher priority than SML crawling results). The
 work queue must be able to filter out duplicate requests and leave only the ones with the
 highest priority.
 - A "fetcher" that grabs action items from the work queue and queries the SMP for the corresponding data of a participant
 - An "indexer" that takes the fetch results and stores them into a searchable index
 - A scheduled "SML retriever" that retrieves the participant list from the SML and stores all entries for updating in the work queue.
 - A REST server implementing the interfaces as defined in chapter 5 and accordingly filling the work queue. Only HTTP requests providing a valid PEPPOL SMP client certificate are accepted.
 - An "auditor" that keeps track of all indexing actions together with some meta information
- 472 The PD Indexer is based on Apache Lucene (https://lucene.apache.org/core/ Apache 2 License) for
- the indexing. The REST interface is to be done with Jersey (https://jersey.java.net/ CDDL 1.1 or GPL
- 474 2 with Classpath exception) like with the SMP.
- 475 **8.1.2 PD Publisher**
- 476 A simple PD Publisher can be built with the ph-oton library (https://github.com/phax/ph-oton -
- 477 Apache 2 License) which offers capabilities to create state of the art (responsive, fast, nice looking)
- web applications quickly. For the main searching Apache Lucene will be used (must be identical to
- 479 the version used for indexing).
- 480 The basic components of the *PD Publisher* are:
- A REST based search interface as described in chapter 6.1
 - A public web page for the simple search
- A public web page for the extended search
- A public web page with the most recently added participants
- A secure web site to see the log and audit entries

186	8.2 SMP-PD interface
187	The PD software suite should ship with a library that can be used to trigger the indexing in the PD
188	Indexer. SMP software providers can use this library to simplify the process of integrating their
189	software with the PD as they just need to call this when relevant information changes (new
190	participant, Business Card update, participant deletion).
191	The Open Source phoss SMP (https://github.com/phax/peppol-smp-server) and other commercial
192	SMP implementations already support the Business Card API.
193	The CIPA SMP server 3.x or newer (https://joinup.ec.europa.eu/software/cipaedelivery/description)
194	cannot be used for PEPPOL because it only supports the OASIS BDXR SMP 1.0 interface and it does
195	not support the required Business Card interface.
